## 1 References and License

We are answering questions in the material from MIT OpenCourseWare course 18.05, Introduction to Probability and Statistics.

Please see the references section for detailed citation information.

The material for the course is licensed under the terms at <http://ocw.mit.edu/terms>.

## 2 *Think* What is $P(S_2 | S_1^c)$

$S_1$  = 'first card is a spade'  $S_2$  = 'second card is a spade'

Therefore  $S_2^c$  = 'second card is not a spade'

We will calculate

$$P(S_2 | S_1^c) \tag{1}$$

That is, we will calculate the probability that the first card is a spade given that the second card is not a spade.

We will apply the same method Orloff and Bloom use in [2], section 3, "Multiplication Rule."

If the first card is a spade then of the 51 cards remaining,  $3 \times 13 = 39$  cards are not spades.

Therefore

$$P(S_2 | S_2^c) = \frac{39}{51} \quad (2)$$

We use the multiplication rule from [2] to compute the same probability.

We apply the multiplication rule letting  $A = S_1$  and  $B = S_2^c$

$$P(S_1 \cap S_2^c) = P(S_1 | S_2^c) \cdot P(S_2^c) \quad (3)$$

$P(S_1) = \frac{13}{52}$  This is because 13 of the 52 cards are spades.

$P(S_2^c) = \frac{39}{52}$  because 39 cards are not spades, and we are dividing by 52 because any of the 39 out of 52 cards are equally likely in all possible sequences of two cards.

$P(S_1 \cap S_2^c) = \frac{13}{52} \frac{39}{51}$  Because there are 13 out of 52 spades to draw for the first card, and 39 out of 51 cards that are not spades to draw for the second card.

We computed  $P(S_1 | S_2^c)$  in equation 2. Now we will solve equation 4 for  $P(S_1 | S_2^c)$ :

$$P(S_1 | S_2^c) = \frac{P(S_1 \cap S_2^c)}{P(S_2^c)} = \frac{\left(\frac{13}{52} \frac{39}{51}\right)}{\frac{39}{52}} = \frac{13}{52} \frac{52}{39} \frac{39}{51} = \frac{13}{51} \quad (4)$$

This is the same result we found in equation 2.

### 3 **Think:** For what other value(s) of $P(A)$ is $A$ independent of itself?

Any value of  $P(A)$  where  $A$  will be independent of itself will satisfy the equation

$$P(A) = P(A)^2 \quad (5)$$

We find this equation in [1].

Therefore members of the set  $\{x | x = x^2, x \in \mathbb{R}\}$  are the values of  $P$  we seek.

We solve for  $x$ :

$$x = x^2 \quad (6)$$

$$\iff -x^2 + x = 0 \quad (7)$$

$$\iff -x(x - 1) = 0 \quad (8)$$

$$\iff x(x-1) = 0 \tag{9}$$

$$\iff x \in \{0, 1\} \tag{10}$$

Therefore another value for  $P(A)$  that is independent of itself is  $P(A) = 1$ . Furthermore, because we solved 6 for  $\{x \in \mathfrak{R}\}$ , these are the only values for  $P(A)$  for which  $A$  is independent of itself. ■
